

Shifting tree growth in response to shifting seasons

Background – Temperate forests across the globe provide critical resources for people.^{1,2} Economically their timber underpins the economies of many states, provinces and countries, with their economic value increasing with climate change through their role in the carbon cycle. Temperate forests currently sequester substantial fossil fuel emissions, offsetting planetary warming.^{3–5}

Yet how long forests can continue to offset fossil fuel emissions depends on how they shift their growth in response to the longer, warmer seasons that come with anthropogenic climate change. Fundamentally, longer seasons should allow trees more time to grow and thus increase their growth, an assumption that was previously supported by several studies.^{6,7} Recently, however, new work suggests trees do not increase growth with longer seasons,⁸ but why and when this happens is a major open question.⁹

My approach – My focus on temporal ecology and shifting seasons with climate change (see *Career narrative*) make me well positioned to address this major open question. Further, my current progress on this question, alongside new datasets^{10,11} and advances in modeling approaches,^{12,13} positions me well to make major progress on it now through a Guggenheim Fellowship.

Over the past three years I have begun to work in-depth on tree growth, including outlining the major potential reasons we may see variability in tree growth with climate change.⁹ It seems clear that the likely reasons tree do not grow more with longer seasons are drought stress (not enough water), heat stress (too high temperatures), or species-specific constraints (some species are simply conservative in their responses, while others are not). But testing these hypotheses has proved much harder because of the complexity of tree growth.

Individual-level tree growth is often highly variable and currently difficult to predict (Fig. 1). For these reasons, most work on radial tree growth to date has worked from stand-level averages, after correcting for age-trends (tree-level

Figure 1: An example of the complexity of tree growth from one *Pinus ponderosa* tree sampled in Utah (USA). Dots show the observed radial growth each year, while the coloring represents estimates from a hierarchical model; shown here is a hierarchical Gaussian process model I may use.¹⁴

allometry).^{15,16}, but less useful for understanding the relative importance of longer seasons. Understanding how longer seasons affects tree growth requires modeling drivers of variability in the time-series of individual trees (Fig. 1) and then build up to understand how different species and stands (sites) respond to longer seasons alongside climate. It effectively requires an entirely new approach to modeling tree growth.

Methods – For my Guggenheim fellowship I propose to develop new models of tree growth that can tease apart how longer seasons, alongside shifting climate, have impacted diverse forests across North America. I have already begun preliminary work on these models (Fig. 1) and am well positioned to complete them for trees across North America during my fellowship.

I propose to work with a leader in hierarchical modeling (Andrew Gelman, Columbia University)¹⁴ and an expert in tree growth and drought (Dr. Benjamin Cook, NASA-GISS/Monash University) to understand how tree growth and forests have shifted in recent decades with longer seasons, and project shifts in the future. I have already identified continental-wide tree growth data¹⁰, climate data since 1896 (start date of robust gridded climate data), and data to estimate the growing season length¹¹. My focus on climate will be critical for understanding how longer seasons affect tree growth outside of the shifting climate that drives longer seasons. Further, it will allow me to forecast from my model to predict how forests will respond to continuing anthropogenic climate change.

Impact – This project will shift our fundamental scientific understanding of how trees grow, yielding our best estimates of radial growth responses to longer seasons. I expect the work will lead to 1-2 papers journal papers (e.g., *Science*, *Nature*) with extensive media coverage. Beyond, I expect this new outlook on tree growth will lead to new experiments, studies and drive new knowledge. Additionally, my multi-scale approach can be extended both outward—to forests in other regions, countries and continents—and temporally downscaled, moving beyond annual resolution to potentially drawing on weekly or daily data (increasingly available through dendrometer networks). Both areas I hope to expand to after my fellowship period.
